

# Three agents move the run. You make the calls.

Scheduling, execution and quality — one agentic layer over the systems you already run

**AUTOMATED** The agent just does it. Nobody has to ask, chase or put it together.

**THRESHOLDED** The agent acts inside limits you set. Outside them it stops and asks.

**A PERSON** Judgement. The agent prepares it — the call is yours.

**Not in scope:** the make process itself — extrusion, tufting, dyeing, backing and finishing. Your MES runs those. These agents sit on top of it. · **Receives** NPI trials from the product workshop.

| WHAT CHANGES |                                                       |                                                          |
|--------------|-------------------------------------------------------|----------------------------------------------------------|
|              | TODAY                                                 | NEXT                                                     |
| UNIT OF WORK | A scheduler rebuilds the sequence by hand             | A scheduler sets the rules; the sequence rebuilds itself |
| FINDING OUT  | At shift handover, from a report someone had to build | In minutes, pushed to the person who can act on it       |
| A DEFECT     | Found at end of line, and argued about later          | Traced to its batch and fed back upstream                |
| CADENCE      | A weekly plan, then a daily firefight                 | Continuous — the plan corrects itself                    |

**THE RULE FOR THE WHOLE SESSION**  
The agents move the run.  
The people make the calls.

**WHAT THE AGENTS NEVER DO**  
Run the line · write the demand plan · grade the product · overrule a quality hold. They read across your systems, hold the plan against what is really happening, and route what matters to the right person — so the decisions that need judgement arrive early, with the options already worked out.

**SITS ON TOP OF WHAT YOU ALREADY RUN**  
Your demand planning · your scheduling system · your MES and batch management · Oracle Fusion · your maintenance system · Databricks. They read across them and write decisions back. They hold no data of their own.

# What each agent does — and where you stay in control

**AUTOMATED** The agent just does it. Nobody has to ask, chase or put it together.

**THRESHOLDED** The agent acts inside limits you set. Outside them it stops and asks.

**A PERSON** Judgement. The agent prepares it — the call is yours.

## 01 Demand into a schedule

Sawyer

Step 01

The demand signal arrives from the system you already run. It becomes a master schedule the plant can actually hold.

**AUTO** Takes the demand signal as given, sizes runs to your batch and dye lot rules, checks the week against available capacity, and rebuilds every cycle.

**LIMIT** Small changes it makes itself. Larger ones, or anything inside the locked window, come to you before the schedule is published.

**PERSON** Signs off the schedule, and decides when an order has to be split.

## 02 Constraints and sequencing

Sawyer

Steps 02–03

Materials, tooling, maintenance and the rates lines are really achieving — then the sequence is set and released to the floor.

**AUTO** Works out what each run needs and when, holds a live picture of what the plant can do, costs the changeovers in each candidate sequence, and releases to execution.

**LIMIT** It can reorder runs inside the rules you set. Anything that breaks a dye lot or a promised date stops and asks.

**PERSON** Approves the released sequence, and owns what it promises.

## 03 Watching the run

Rowan

Step 04

Your MES runs the make. The agent reads it continuously and holds the released plan against what is actually happening.

**AUTO** Tracks output, rate, downtime and yield against the released plan, keeps every KPI current, and produces the report without anyone building it.

**LIMIT** Drift inside your band it simply logs. Beyond it, the alert goes out.

**PERSON** Sets what "on track" means, and what is worth being told about.

## 04 Exceptions and escalation

Rowan

Steps 05–06

A line slows, a machine stops, a batch goes on hold. Who needs to know, how fast, and what moves around it?

**AUTO** Picks up the deviation, works out the effect on the finish date, alerts the line and plant manager, and tells the scheduling agent to re-plan.

**LIMIT** It can reshuffle the rest of the day on its own. Anything that would miss a customer date stops and asks.

**PERSON** Decides which matters more — the dye lot or the date.

## 05 Quality at end of line

Wren

Steps 07–08

Inspection sits at the end of the line. First quality or seconds — the call that costs margin rather than time.

**AUTO** Reads the inspection result against spec, links each roll to its batch and run record, and proposes the grade.

**LIMIT** Clear passes it grades itself. Anything borderline, or a fault seen more than once, goes to a person.

**PERSON** Decides the grade, and what happens to what fails.

## 06 Claims, traceback and the loop

Wren

Step 09

A claim comes back from the field. Which batch, which run, which line — and what changes so it does not happen again.

**AUTO** Traces the claim back to the batch and the run that made it, pulls the records already held, and sends the finding to the scheduling and make agents.

**LIMIT** A one-off it records and watches. A pattern across batches is raised as a process change.

**PERSON** Decides what the real cause was, and what changes because of it.
